

Computational Modeling of Drug Transport Across the Blood Brain Barrier

ALEX

Introduction

- The blood-brain barrier (BBB) prevents >98% of therapeutics from reaching the CNS
- Effective drug delivery to the brain is a major challenge in neuroscience and pharmacology
- Understanding transport mechanisms is key for designing therapeutics and nanoparticle carriers

Methods

- Computational Modeling
 - Differential equations to simulate transport kinetics
 - Stochastic diffusion models to represent molecular behavior
- Molecular Feature Analysis
 - Machine learning to identify features enhancing BBB permeability

Objectives

- Develop a computational framework to simulate BBB transport
- Quantify diffusion of nanoparticles and biologically derived molecules with varying size, shape, and surface chemistry
- Integrate existing experimental data and stochastic modeling for predictive insights

Data Results Findings

Results Conclusions

Applications

- Accelerate CNS drug development by overcoming BBB limitations
- Open-source simulation platform for research and education
- Tool in predicting targeted drug delivery, neurodegenerative disease diagnostics, and synthetic biology and biomaterials research
